

Introduction to Machine Learning: Linear and Logistic Regression and Neural Networks Using Python

Chapter 4 Linear and Logistic Regression

Linear and Logistic Regression

Section	Title	Description
4.1	Linear Regression: Normal Equations	This section presents the normal equations solution for linear regression
4.2	Linear Regression: Mathematical Foundations	This section describes a general mathematical approach for linear regression, which will be used for other approaches discussed in this course
4.3	Derivative Testing	This section presents an algorithm for derivative testing
4.4	Code Overview	This section gives a general overview of framework to be built in this course
4.5	Code Walkthrough Version 1.1	This section gives a walkthrough of the initial version of the framework, including functionality for derivative testing
4.6	Code Walkthrough Version 1.2	This sections describes updates to the framework to handle training. The code walkthrough shows the updates and shows examples of linear regression.
4.7	Logistic Regression: Mathematical Foundations	This section extends the mathematical approach to logistic regression
4.8	Code Walkthrough Version 1.3	This section describes updates to extend the code framework to handle logistic regression. The code walkthrough shows the updates and examples.

4.1 Linear Regression: Normal Equations

Linear Regression: Normal Equations

Goal of this Section:

- Present the normal equations solution for linear regression

Linear Regression – Line Fitting

Training Data:

- Input information: X values
- Output information: Y values

Linear Regression Goal:

- Find straight line that best fits the training data

Prediction:

- Use line to predict Y values given new input X values

Why start with Linear Regression?

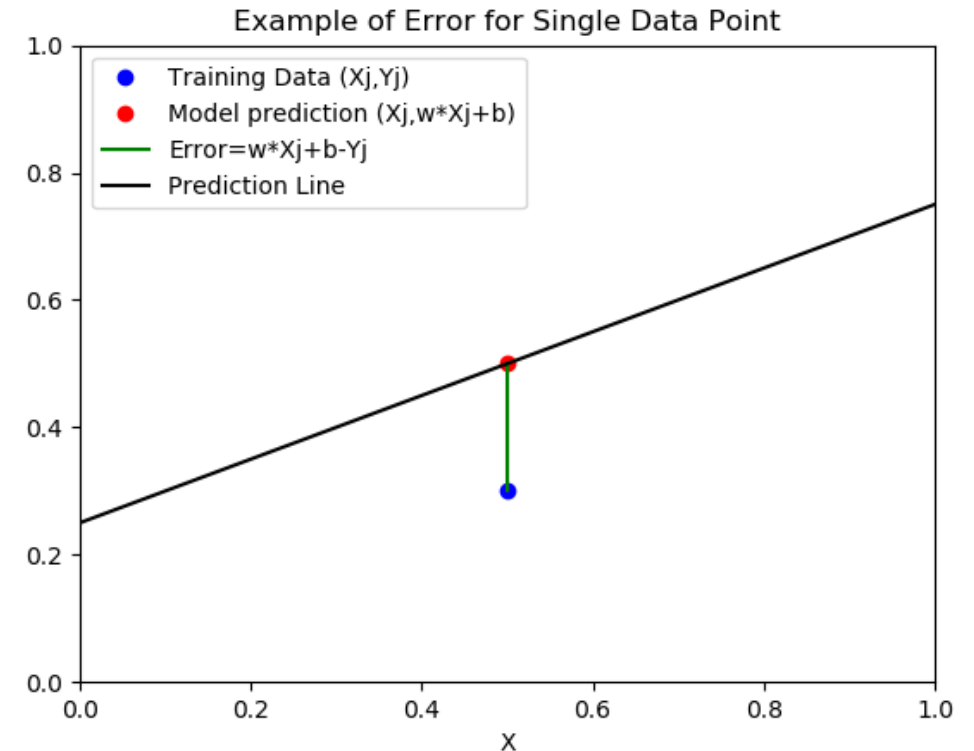

- Simple problem with well known solution
- Ultimately, this course will present a general approach that can also be applied to Logistic Regression and Neural Networks

Least Squares Approach

- Assume input/output info $(X_0, Y_0), (X_1, Y_1), \dots, (X_{m-1}, Y_{m-1})$
- Assume $Y = WX + b$
- Least squares approach: find W and b that minimize sum of squared error:

$$L = \sum_{j=0}^{m-1} (WX_j + b - Y_j)^2$$

Normal Equations

- For the 1-dimensional problem input/output info: $(X_0, Y_0), (X_1, Y_1), \dots, (X_{m-1}, Y_{m-1})$

- Let us define:

$$\hat{X} = \begin{bmatrix} X_0 & X_1 & \dots & X_{m-1} \\ 1 & 1 & \dots & 1 \end{bmatrix} \quad \text{and} \quad Y = [Y_0 \quad Y_1 \quad \dots \quad Y_{m-1}]$$

- Define the parameter vector as:

$$\hat{W} = [W \quad b]$$

- The least squares normal equations solution is (T signifies transpose and -1 is the inverse)

$$\hat{W} = (Y \hat{X}^T)(\hat{X} \hat{X}^T)^{-1}$$

(Note: this formula is different from what you have probably seen. In typical linear algebra courses, Y and w are column vectors. The above formula is the transpose of the typical formula from courses.)

- This solution is obtained by setting $\frac{\partial L}{\partial W} = 0$ and $\frac{\partial L}{\partial b} = 0$
- This approach can be generalized to higher dimensions
- See for example: https://en.wikipedia.org/wiki/Ordinary_least_squares

4.1 Normal Equations – Jupyter Notebook DEMO

- Open file IntroML/Examples/Chapter4/NormalEquations.ipynb

Course Resources at:

- <https://github.com/satishchandrareddy/IntroML/>

4.2 Linear Regression: Mathematical Foundations

Linear Regression: Mathematical Foundations

Goal of this Section:

- Present the mathematical foundations for the machine learning approach for linear regression, including:
 - Format of training data
 - Function structure and parameters
 - Loss function
 - Training algorithm
 - Prediction algorithm

Linear Regression – Line Fitting

Training Data:

- Input information: X values
- Output information: Y values

Linear Regression Goal:

- Find straight line that best fits the training data

Prediction:

- Use line to predict Y values given new input X values

Linear Regression: General Approach

Goal of Supervised Learning: find a function that maps input information to output information and then use function to make predictions

General approach has following components and phases:

(1) Training Data

(2) Function Structure

- Defines general form of the function with unknown parameters
- Process of applying function structure is called Forward Propagation

(3) Loss Function

- Used to measure effectiveness of function structure and choice of parameters

(4) Training Phase

- Uses optimization to determine function parameters that minimize loss function for training data
- Process of computing derivatives is called Back Propagation

(5) Prediction Phase

- Applies forward propagation using parameters determined in Training Phase to predict outputs when new input data is provided

Training Data

- Data point j : input information (feature) vector: $\begin{bmatrix} X_{0,j} \\ X_{1,j} \\ \vdots \\ X_{d-1,j} \end{bmatrix}$ and output: Y_j
- Define the feature matrix ($d \times m$) and output vector ($1 \times m$):

$$X = \begin{bmatrix} X_{00} & \dots & X_{0,m-1} \\ \dots & \dots & \dots \\ X_{d-1,0} & \dots & X_{d-1,m-1} \end{bmatrix} \quad Y = [Y_0 \quad \dots \quad Y_{m-1}]$$

Training Data – Example Points in Plane

- For the 1-dimensional least squares problem in the motivating example, the training data consists of points in the plane: $(X_0, Y_0), (X_1, Y_1), \dots, (X_{m-1}, Y_{m-1})$
- For example consider 4 samples in training set: $(1,1), (0.5,2), (2,3), (4,2)$
- In this case each data point has 1 feature (the X value)
- Feature matrix and output vector are:

$$X = [1 \quad 0.5 \quad 2 \quad 4] \quad Y = [1 \quad 2 \quad 3 \quad 2]$$

Training Data – Example Predicting House Prices

- Suppose we have input information (features) of a house and output information (price)

Feature 0: Lot area (in square feet)

Feature 1: House area (in square feet)

Feature 2: Number of bathrooms

Feature 3: Number of floors

Feature ...:

Feature d-1: Size of garage (number of cars)

- Data point j: feature vector: $\begin{bmatrix} 5000 \\ 2000 \\ 3 \\ 2 \\ \dots \\ 2 \end{bmatrix}$ and output information (price): $Y_j = 800,000$

- Collect all feature vectors and output values to create feature matrix and output vector

Function Structure - Forward Propagation

Forward Propagation is name applied to process of estimating output values using function structure

Input: feature matrix X (d x m d features and m data points)

Assign: parameter vector $W = [W_0 \quad W_1 \quad \dots \quad W_{d-1}]$ and b

1. Linear part: for $j=0, \dots, m-1$

$$Z_j = W_0 X_{0j} + W_1 X_{1j} + W_2 X_{2j} + \dots + W_{d-1} X_{d-1j} + b$$

In vector form $Z = [Z_0 \quad Z_1 \quad \dots \quad Z_{m-1}]$ and $Z = WX + b$

2. Activation: apply function $f(z)$ to each component of Z :

$$A_j = f(Z_j) \quad j = 0, \dots, m-1$$

For Linear Regression $f(z) = z$, so $A_j = Z_j, \quad j = 0, \dots, m-1$

$[A_0 \quad A_1 \quad \dots \quad A_{m-1}]$ is estimate of output values

Function Structure

Forward Propagation Diagram

Forward Propagation - Example

- Consider a case of 2 features and 3 data points ($m=3$)

$$X = \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} \quad Y = [8 \quad 6 \quad 10]$$

- Assume that initial parameter values are:

$$W = [1 \quad 1] \quad b = [2]$$

- Forward Propagation:

$$Z = WX + b = [1 \quad 1] \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} + [2] = [5 \quad 9 \quad 13]$$

$$A = Z = [5 \quad 9 \quad 13]$$

Loss Function

- Loss function used to measure effectiveness of choice W and b
- Standard approach for Linear regression is to use Mean Squared Error function:

$$Loss = L = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2$$

- $A_j - Y_j$ is the error between the original training data point and the prediction based on the function structure and forward propagation
- Loss is mean of squares of errors for all training points

Loss Function - Example

- Consider a case of 2 features and 3 data points ($m=3$)

$$X = \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} \quad Y = [8 \quad 6 \quad 10]$$

- From the Forward Propagation Example

$$A = [5 \quad 9 \quad 13]$$

- Loss function defined by

$$L = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2 = \frac{1}{3} \sum_{j=0}^{m-1} [(5 - 8)^2 + (9 - 6)^2 + (13 - 10)^2] = 9$$

Training Phase

- Training phase attempts to find suitable coefficients W and b by minimizing loss function when applied to training data
- From multi-variable calculus, Loss function has a local minimum when the gradients are 0

$$\nabla_W L = 0 \text{ and } \nabla_b L = 0$$

- Can solve these equations analytically for Linear Regression, but not in general case (Logistic Regression and Neural Networks)
 - Can show solution for Linear Regression leads to normal equations solution
- Use optimization algorithm (example: Gradient Descent) to minimize Loss function
 - Need to compute the above gradients

Computing Gradients

Recall the chain rule lecture (Section 3.2)

- If $L = L(Z_0, \dots, Z_{m-1})$ and $Z = WX + b$, then

$$\nabla_W L = \nabla_Z L X^T \quad \text{and} \quad \nabla_b L = \sum_{j=0}^{m-1} \nabla_Z L_j$$

- For linear regression, the loss function L depends on A_0, \dots, A_{m-1}
- A_0 depends exclusively on Z_0 , A_1 depends exclusively on Z_1 and so on
- In fact $\frac{\partial A_j}{\partial Z_j} = 1$ since the activation function is the identity $f(z)=z$
- To compute the derivatives correctly, we need to again apply the chain rule

$$\nabla_Z L = \left[\frac{\partial L}{\partial Z_0} \quad \dots \quad \frac{\partial L}{\partial Z_{m-1}} \right] = \left[\frac{\partial L}{\partial A_0} \frac{\partial A_0}{\partial Z_0} \quad \frac{\partial L}{\partial A_1} \frac{\partial A_1}{\partial Z_1} \quad \dots \quad \frac{\partial L}{\partial A_{m-1}} \frac{\partial A_{m-1}}{\partial Z_{m-1}} \right]$$

$$\nabla_Z L = \left[\frac{\partial L}{\partial A_0} \quad \frac{\partial L}{\partial A_1} \quad \dots \quad \frac{\partial L}{\partial A_{m-1}} \right] * \left[\frac{\partial A_0}{\partial Z_0} \quad \frac{\partial A_1}{\partial Z_1} \quad \dots \quad \frac{\partial A_{m-1}}{\partial Z_{m-1}} \right] = \nabla_A L * [1 \quad 1 \quad \dots \quad 1]$$

Here $*$ means component-wise multiplication

Gradient of Mean Squared Error Function

- For the mean squared error function:

$$L = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2$$

- Gradient given by

$$\nabla_A L = \left[\frac{\partial L}{\partial A_0} \quad \frac{\partial L}{\partial A_1} \quad \dots \quad \frac{\partial L}{\partial A_{m-1}} \right] \text{ where } \frac{\partial L}{\partial A_j} = \frac{2}{m} (A_j - Y_j) \text{ for } j=0, \dots, m-1$$

Back Propagation Algorithm

Back propagation is the process of computing $\nabla_W L$ and $\nabla_b L$

Assume that forward propagation has taken place so $[A_0 \ A_1 \ \dots \ A_{m-1}]$ has been computed

Input: feature matrix X and value vector Y

1. Compute gradient of L with respect to A

$$\nabla_A L = \left[\frac{\partial L}{\partial A_0} \quad \frac{\partial L}{\partial A_1} \quad \dots \quad \frac{\partial L}{\partial A_{m-1}} \right], \quad \frac{\partial L}{\partial A_j} = \frac{2}{m} (A_j - Y_j), \quad j = 0, \dots, m-1$$

2. Compute derivatives of A wrt Z : $\frac{\partial A_j}{\partial Z_j} = 1, j = 0, \dots, m-1$

3. Compute gradient L with respect to Z :

$$\nabla_Z L = \nabla_A L * \left[\frac{\partial A_0}{\partial Z_0} \quad \frac{\partial A_1}{\partial Z_1} \quad \dots \quad \frac{\partial A_{m-1}}{\partial Z_{m-1}} \right] \text{ (component-wise multiplication)}$$

4. Compute gradient of L with respect to W and b :

$$\nabla_W L = \nabla_Z L X^T, \quad \nabla_b L = \sum_{j=0}^{m-1} \nabla_Z L_j$$

Back Propagation - Example

- Consider a case of 2 features and 3 data points ($m=3$)

$$X = \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} \quad Y = [8 \quad 6 \quad 10]$$

- Assume that initial parameter values are:

$$W = [1 \quad 1] \quad b = [2]$$

- From forward propagation example:

$$A = Z = [5 \quad 9 \quad 13]$$

- Gradient of Loss with respect to A:

$$\frac{\partial L}{\partial A_j} = \frac{2}{m} (A_j - Y_j) \text{ for } j=0, \dots, m-1 \quad \nabla_A L = \left[\frac{2}{3} (5 - 8) \quad \frac{2}{3} (9 - 6) \quad \frac{2}{3} (13 - 10) \right] = [-2 \quad 2 \quad 2]$$

$$\left[\frac{\partial A_0}{\partial Z_0} \quad \frac{\partial A_1}{\partial Z_1} \quad \frac{\partial A_2}{\partial Z_2} \right] = [1 \quad 1 \quad 1]$$

$$\nabla_Z L = \nabla_A L * \left[\frac{\partial A_0}{\partial Z_0} \quad \frac{\partial A_1}{\partial Z_1} \quad \frac{\partial A_2}{\partial Z_2} \right] = [-2 \quad 2 \quad 2] * [1 \quad 1 \quad 1] = [-2 \quad 2 \quad 2] \text{ (component-wise multiplication)}$$

$$\nabla_W L = \nabla_Z L X^T = [-2 \quad 2 \quad 2] \begin{bmatrix} 1 & 2 \\ 2 & 5 \\ 4 & 7 \end{bmatrix} = [10 \quad 20]$$

$$\nabla_b L = \sum_{j=0}^{m-1} \nabla_Z L_j = 2 \text{ (sum of entries of } \nabla_b L)$$

Training Algorithm

- Training algorithm uses Gradient Descent to find parameters W and b that minimize the Loss function
- At each step of gradient descent need to compute gradient of loss with respect to W and b
- Computation of gradient involves both forward and back propagation

Training Algorithm

Input training data: feature matrix X and values Y

Make initial guess for parameters $W_{\text{epoch}=0}$ and $b_{\text{epoch}=0}$

Choose learning rate $\alpha > 0$

1. Loop for epoch $i = 1, 2, \dots$

- Forward Propagate using X to compute $A_{\text{epoch}=i-1}$
- Back Propagate using X , Y , and $A_{\text{epoch}=i-1}$ to compute $\nabla_W L_{\text{epoch}=i-1}, \nabla_b L_{\text{epoch}=i-1}$

- Update parameters: (Gradient Descent)

$$W_{\text{epoch}=i} = W_{\text{epoch}=i-1} - \alpha \nabla_W L_{\text{epoch}=i-1}$$

$$b_{\text{epoch}=i} = b_{\text{epoch}=i-1} - \alpha \nabla_b L_{\text{epoch}=i-1}$$

- Forward Propagate to compute $A_{\text{epoch}=i}$
- Compute Loss at $A_{\text{epoch}=i}$

Loop for fixed number of epochs (or if Loss reduced sufficiently)

Training Algorithm

- With initial W and b use Forward Propagation to compute A
- Use Back Propagation to compute gradients
- Use Gradient Descent to update parameters
- Process is repeated

Training Algorithm - Example

- Consider a case of 2 features and 3 data points ($m=3$)

$$X = \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} \quad Y = [8 \quad 6 \quad 10]$$

- Assume that initial parameter values are:

$$W_{epoch=0} = [1 \quad 1] \quad b_{epoch=0} = [2]$$

- Choose learning rate $\alpha=0.01$

EPOCH 1

- From Forward Propagation Example:

$$A_{epoch=0} = [5 \quad 9 \quad 13]$$

- From Back Propagation Example:

$$\nabla_W L_{epoch=0} = [10 \quad 20], \quad \nabla_b L_{epoch=0} = [2]$$

- Update:

$$W_{epoch=1} = W_{epoch=0} - \alpha \nabla_W L_{epoch=0} = [1 \quad 1] - 0.01 * [10 \quad 20] = [0.9 \quad 0.8]$$

$$b_{epoch=1} = b_{epoch=0} - \alpha \nabla_b L_{epoch=0} = [2] - 0.01 * [2] = [1.98]$$

Training Algorithm - Example

- Apply Forward Propagation with $W_{epoch=1}$ and $b_{epoch=1}$

$$A_{epoch=1} = Z_{epoch=1} = W_{epoch=1}X + b_{epoch=1} = [0.9 \quad 0.8] \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} + [1.98] = [4.48 \quad 7.78 \quad 11.18]$$

$$Loss_{epoch=1} = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2 = \frac{1}{3} [(-3.52)^2 + 1.78^2 + 1.18^2] = 5.6504$$

EPOCH 2

- Forward propagation has been applied above to compute $A_{epoch=1} = [4.48 \quad 7.78 \quad 11.18]$
- Apply Back Propagation to compute $\nabla_W L_{epoch=1}, \nabla_b L_{epoch=1}$

$$\frac{\partial L}{\partial A_j} = \frac{2}{m} (A_j - Y_j) \text{ for } j=0, \dots, m-1 \quad \nabla_A L = \left[\frac{2}{3} (4.48 - 8) \quad \frac{2}{3} (7.78 - 6) \quad \frac{2}{3} (11.18 - 10) \right] =$$
$$[-2.3467 \quad 1.1867 \quad 0.7867]$$

$$\begin{bmatrix} \frac{\partial A_0}{\partial Z_0} & \frac{\partial A_1}{\partial Z_1} & \frac{\partial A_2}{\partial Z_2} \end{bmatrix} = [1 \quad 1 \quad 1]$$

$$\nabla_Z L = \nabla_A L * \begin{bmatrix} \frac{\partial A_0}{\partial Z_0} & \frac{\partial A_1}{\partial Z_1} & \frac{\partial A_2}{\partial Z_2} \end{bmatrix} = [-2.3467 \quad 1.1867 \quad 0.7867] * [1 \quad 1 \quad 1] = [-2.3467 \quad 1.1867 \quad 0.7867]$$

$$\nabla_W L = \nabla_Z L X^T = [-2.3467 \quad 1.1867 \quad 0.7867] \begin{bmatrix} 1 & 2 \\ 2 & 5 \\ 4 & 7 \end{bmatrix} = [3.1733 \quad 6.7467]$$

$$\nabla_b L = \sum_{j=0}^{m-1} \nabla_Z L_j = [-0.3733]$$

Training Algorithm - Example

- Update:

$$W_{epoch=2} = W_{epoch=1} - \alpha \nabla_W L_{epoch=1} = [0.9 \quad 0.8] - 0.01 * [3.1733 \quad 6.7467] = [0.8683 \quad 0.7325]$$

$$b_{epoch=2} = b_{epoch=1} - \alpha \nabla_b L_{epoch=1} = [1.98] - 0.01 * [-0.3733] = [1.9837]$$

- Apply Forward Propagation with $W_{epoch=2}$ and $b_{epoch=2}$

$$A_{epoch=2} = Z_{epoch=2} = W_{epoch=2}X + b_{epoch=2} = [0.8686 \quad 0.7325] \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} + [1.9837] \\ = [4.3171 \quad 7.3829 \quad 10.5845]$$

$$Loss_{epoch=2} = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2 = \frac{1}{3} [(-3.6829)^2 + 1.3829^2 + 0.5845^2] = 5.2727$$

- Loss dropped from 5.6504 in EPOCH 1 to 5.2727 in EPOCH 2
- In general will use trial and error to adjust learning rate α

Prediction Algorithm

Prediction algorithm makes use parameters computed in Training Algorithm

Input new input feature matrix \tilde{X} ($d \times p$ - d features and p samples)

Use W and b computed by Training Algorithm

1. Perform Forward Propagation to compute output \tilde{A}

Prediction is \tilde{A} ($1 \times p$ values)

Prediction Algorithm - Example

- From Training Algorithm Example:

$$X = \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} \quad Y = [8 \quad 6 \quad 10]$$

- After 2 EPOCHs of Training Algorithm:

$$W_{epoch=2} = [0.8683 \quad 0.7325] \quad b_{epoch=2} = [1.9837]$$

- Prediction: Apply Forward Propagation with $W_{epoch=2}$ and $b_{epoch=2}$

$$\begin{aligned} A_{epoch=2} = Z_{epoch=2} &= W_{epoch=2}X + b_{epoch=2} = [0.8683 \quad 0.7325] \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} + [1.9837] \\ &= [4.3170 \quad 7.3828 \quad 10.5844] \end{aligned}$$

Accuracy Calculation

- Accuracy calculation compares value vector \tilde{Y} to prediction
- Can use Mean Squared Error function to measure accuracy for regression
 - Mean Squared Error is not as informative for Classification as for Regression so a different measure will be introduced later in the chapter
- In this section, use Mean Absolute Error

Assume Training has been performed

Assume Prediction Algorithm has been applied to yield value vector \tilde{A}

1. Accuracy defined by mean absolute error

$$Accuracy = \frac{1}{m} \sum_{j=0}^{m-1} |\tilde{A}_j - \tilde{Y}_j|$$

Accuracy Calculation - Example

- From prediction example:

$$X = \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} \quad Y = [8 \quad 6 \quad 10]$$

- Prediction:

$$A_{epoch=2} = [4.3170 \quad 7.3828 \quad 10.5844]$$

- Accuracy:

$$Accuracy = \frac{1}{m} \sum_{j=0}^{m-1} |A_j - Y_j| = \frac{1}{3} [| -3.6830 | + | 1.3828 | + | 0.5844 |] = 1.8834$$

Linear Regression – Summary

Component	Algorithm	Details
Training Data		Input m data points: X (dxm-dimensional feature matrix) Y vector of values (1xm)
Function Structure	Forward Propagation	Linear: $Z = WX + b$ (Z is row vector of length m, W is row vector of length d, b is scalar) Activation function: $f(z) = z$ $A = f(Z)$ (1xm)
Loss Function		Mean Squared Error: $L = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2$
Derivative	Back Propagation	Compute gradients $\nabla_W L$ and $\nabla_b L$
Training	Fitting using Gradient Descent to minimize Loss	Find W, b that minimizes loss Initial guess: $W_{epoch=0}, b_{epoch=0}$ Choose Learning Rate: $\alpha > 0$ For epoch=1,2,3... (for fixed number of epochs) apply forward and back propagation to compute $\nabla_W L_{epoch=i-1}, \nabla_b L_{epoch=i-1}$ $W_{epoch=i} = W_{epoch=i-1} - \alpha \nabla_W L_{epoch=i-1}$ $b_{epoch=i} = b_{epoch=i-1} - \alpha \nabla_b L_{epoch=i-1}$
Prediction	Apply Forward Propagation	Using computed W and b from Training Algorithm Given new input feature matrix \tilde{X} Perform Forward Propagation to compute \tilde{A} , the prediction for values

4.2 Linear Regression – Jupyter Notebook DEMO

- Open file IntroML/Examples/Chapter4/LinearRegression.ipynb
- Has examples of
 - Forward Propagation
 - Loss Function
 - Backward Propagation
 - Training Algorithm
 - Prediction Algorithm
 - Accuracy Calculation

Course Resources at:

4.3 Derivative Testing

Derivative Testing

Goal of this Section:

- Present testing algorithm for comparing gradients computed using forward/back propagation with approximate estimates

Motivation for Derivative Testing

- The forward/back propagation approach for computing gradients described in the previous section has a number of steps
- The formulas for neural networks presented in the next chapter are more complicated
- To gain confidence in machine learning framework to be developed in course, it is useful to provide a check of the gradients produced by forward/back propagation

Difference Formula for Derivatives

- Let $L = L(p_0, p_1, p_2, \dots, p_d)$. Definition of partial derivative is:

$$\frac{\partial L}{\partial p_i} = \lim_{\varepsilon \rightarrow 0} \frac{L(p_0, p_1, \dots, p_i + \varepsilon, \dots, p_d) - L(p_0, p_1, \dots, p_i, \dots, p_d)}{\varepsilon}$$

- Forward difference formula: pick small ε (eg: 10^{-5}) - error proportional to ε or better as $\varepsilon \rightarrow 0$)

$$\frac{\partial L}{\partial p_i} \approx \frac{L(p_0, p_1, \dots, p_i + \varepsilon, \dots, p_d) - L(p_0, p_1, \dots, p_i, \dots, p_d)}{\varepsilon}$$

- Centered differences formula: (error is proportional to ε^2 or better as $\varepsilon \rightarrow 0$ – this is more accurate!)

$$\frac{\partial L}{\partial p_i} \approx \frac{L(p_0, p_1, \dots, p_i + \varepsilon, \dots, p_d) - L(p_0, p_1, \dots, p_i - \varepsilon, \dots, p_d)}{2\varepsilon}$$

- Apply centered differences approach for each variable (apply $d+1$ times)

Derivative Testing - Example

- Consider Backpropagation Example in Section 4.2

$$X = \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} \quad Y = [8 \quad 6 \quad 10] \quad W = [1 \quad 1] \quad b = [2]$$

- From the Back Propagation example of Section 4.2, we have

$$\frac{\partial L}{\partial W_0} = 10, \frac{\partial L}{\partial W_1} = 20, \frac{\partial L}{\partial b} = 2$$

- Approximate $\frac{\partial L}{\partial W_0}$ by bumping W_0 by plus $+\varepsilon$ and $-\varepsilon$ (choose $\varepsilon=0.1$)

- $\varepsilon=0.1$ case:

$$Z = WX + b = [1.1 \quad 1] \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} + [2] = [5.1 \quad 9.2 \quad 13.4] \quad A = Z$$

$$L(W_0 + \varepsilon) = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2 = \frac{1}{3} ((-2.9)^2 + 3.2^2 + 3.4^2) = 10.07$$

- $\varepsilon=-0.1$ case:

$$Z = WX + b = [0.9 \quad 1] \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} + [2] = [4.9 \quad 8.8 \quad 12.6] \quad A = Z$$

$$L(W_0 - \varepsilon) = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2 = \frac{1}{3} ((-3.1)^2 + 2.8^2 + 2.6^2) = 8.07$$

Hence:

$$\frac{\partial L}{\partial W_0} \approx \frac{L(W_0 + \varepsilon) - L(W_0 - \varepsilon)}{2\varepsilon} = \frac{10.07 - 8.07}{2(0.1)} = 10 \quad (\text{this matches back propagation derivative exactly})$$

Derivative Testing - Example

- Approximate $\frac{\partial L}{\partial W_1}$ by bumping W_1 by plus $+\varepsilon$ and $-\varepsilon$ (choose $\varepsilon=0.1$)

- $\varepsilon=0.1$ case:

$$Z = WX + b = [1 \quad \mathbf{1.1}] \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} + [2] = [5.2 \quad 9.5 \quad 13.7] \quad A = Z$$

$$L(W_1 + \varepsilon) = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2 = \frac{1}{3} ((-2.8)^2 + 3.5^2 + 3.7^2) = 11.26$$

- $\varepsilon=-0.1$ case:

$$Z = WX + b = [1 \quad \mathbf{0.9}] \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} + [2] = [4.8 \quad 8.5 \quad 12.3] \quad A = Z$$

$$L(W_1 - \varepsilon) = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2 = \frac{1}{3} ((-3.2)^2 + 2.5^2 + 2.3^2) = 7.26$$

Hence:

$$\frac{\partial L}{\partial W_1} \approx \frac{L(W_1 + \varepsilon) - L(W_1 - \varepsilon)}{2\varepsilon} = \frac{11.26 - 7.26}{2(0.1)} = 20 \quad (\text{this matches back propagation derivative exactly})$$

Derivative Testing - Example

- Approximate $\frac{\partial L}{\partial b}$ by bumping b by plus $+\varepsilon$ and $-\varepsilon$ (choose $\varepsilon=0.1$)
- $\varepsilon=0.1$ case:

$$Z = WX + b = \begin{bmatrix} 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} + \begin{bmatrix} 2.1 \end{bmatrix} = \begin{bmatrix} 5.1 & 9.1 & 13.1 \end{bmatrix} \quad A = Z$$

$$L(b+\varepsilon) = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2 = \frac{1}{3} ((-2.9)^2 + 3.1^2 + 3.1^2) = 9.21$$

- $\varepsilon=-0.1$ case:

$$Z = WX + b = \begin{bmatrix} 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 2 & 4 \\ 2 & 5 & 7 \end{bmatrix} + \begin{bmatrix} 1.9 \end{bmatrix} = \begin{bmatrix} 4.9 & 8.9 & 12.9 \end{bmatrix} \quad A = Z$$

$$L(b+\varepsilon) = \frac{1}{m} \sum_{j=0}^{m-1} (A_j - Y_j)^2 = \frac{1}{3} ((-3.1)^2 + 2.9^2 + 2.9^2) = 8.81$$

Hence:

$$\frac{\partial L}{\partial b} \approx \frac{L(b+\varepsilon) - L(b-\varepsilon)}{2\varepsilon} = \frac{9.21 - 8.81}{2(0.1)} = 2 \quad (\text{this matches back propagation derivative exactly})$$

- Approximations match derivatives exactly – this occurs for linear regression as Loss depends quadratically on parameters W and b , but will not occur for Logistic Regression and Neural Network, in general, because activation and loss functions are more complicated

Concatenating and Loading Parameters

- To efficiently bump each parameter it is convenient to store all parameters in a single vector
- Concatenation combines all parameters:

Original format: $W = [W_0 \ W_1 \ \dots \ W_{d-1}]$ and scalar b

Concatenated format: $[W_0 \ W_1 \ \dots \ W_{d-1} \ b]$ (vector with all parameters)

- Process of loading takes parameters in concatenated form and puts parameters back into original format (separate W and b)
- Testing approach:
 - Use concatenated form to bump parameters
 - Put back into original format to perform forward propagate and compute Loss after parameters are bumped

Derivative Testing Algorithm

Assign $W = [W_0 \ W_1 \ \dots \ W_{d-1}]$ and scalar b

Input Training Data: feature matrix X and values Y

1. Perform Forward and Back Propagation to compute $\nabla_W L, \nabla_b L$
2. Concatenate original parameters $W, b \rightarrow [W_0 \ W_1 \ \dots \ W_{d-1} \ b]$
3. Concatenate gradients $\nabla_W L, \nabla_b L \rightarrow \left[\frac{\partial L}{\partial W_0} \ \dots \ \frac{\partial L}{\partial W_{d-1}} \ \frac{\partial L}{\partial b} \right]$
4. Loop over $i = 0, 1, \dots, d$ ($d+1$ parameters in concatenated list)
 - Add ε to parameter p_i in original concatenated parameter list
 - Load parameters back into W and b
 - Forward propagate and compute Loss $L(p_i + \varepsilon)$
 - Subtract ε from parameter p_i in original concatenated parameter list
 - Load parameters back into W and b
 - Forward propagate and compute Loss $L(p_i - \varepsilon)$
 - Estimate partial derivative with respect to i 'th parameter is $(L(p_i + \varepsilon) - L(p_i - \varepsilon))/2\varepsilon$
4. Compare estimated partial derivatives to those computed in Steps 3

4.3 Derivative Testing – Jupyter Notebook DEMO

- Open file IntroML/Examples/Chapter4/DerivativeTesting.ipynb

Course Resources at:

- <https://github.com/satishchandrareddy/IntroML/>

4.4 Code Overview

Coding Overview

Goal of this Section:

- Present overview of course framework design, including
 - Principal classes employed
 - Format of numpy arrays

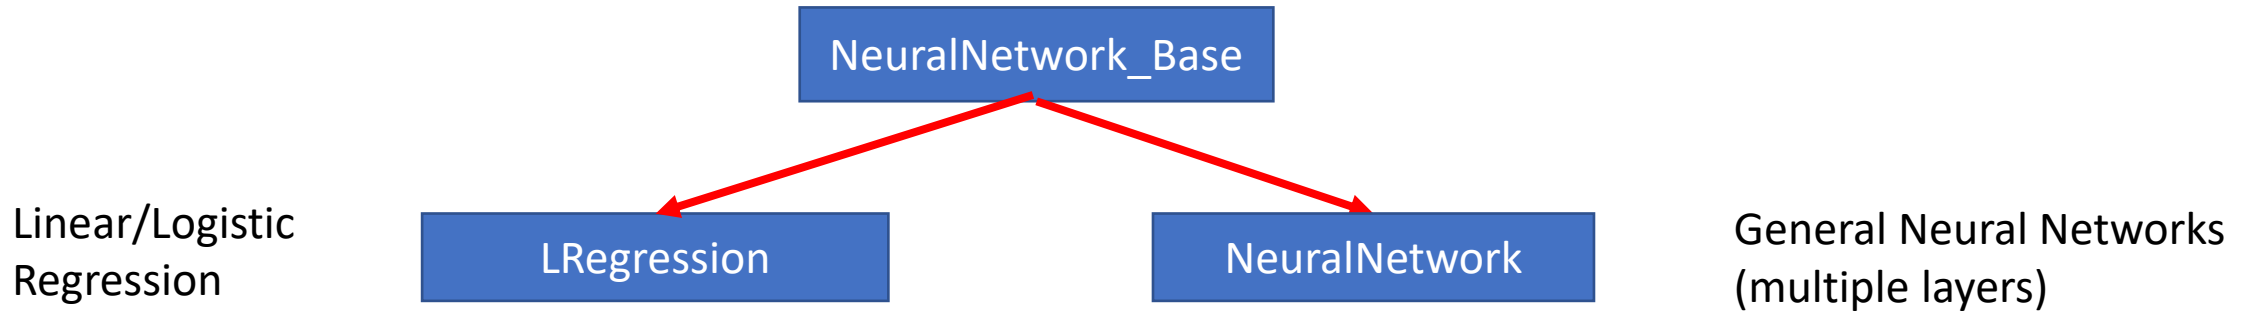

Machine Learning Framework

A machine learning framework consists of building blocks for designing, training and validating deep neural networks, through a high level programming interface

Code Overview

- Course framework will be built using object oriented approach
- Two principal classes
 - `NeuralNetwork_Base`
 - This class consists of building blocks to create and train and predict with Linear Regression, Logistic Regression, and Neural Network models
 - `Optimizer_Base`
 - This class consists of code used for optimization (minimizing the loss function)
- Broad Design considerations:
 - Numpy array is key building block
 - Use numpy functionality to operate on arrays without explicit looping
 - Use interfaces for framework Tensorflow as a rough guide
- Additional codes
 - Activation functions
 - Loss functions
 - Plotting functions
 - Unit test
 - Drivers
 - Load Data functions

Code Overview: NeuralNetwork_Base Class

Key Methods

- Forward Propagation
- Back Propagation
- Compute Loss
- Fit (for training)
- Predict
- Accuracy
- Test Derivative
- Concatenate Parameters
- Load Parameters

Will attempt to create methods as general as possible so that they can be used for both Linear/Logistic Regression and Neural Networks

Code Overview: Optimizer_Base Class

Key Methods

- Update

Code Overview - Numpy Arrays

All relevant arrays will be defined explicitly as 2d numpy arrays

- Feature Matrix X
 - This naturally is a 2d object ($d \times m$) (number of features \times number of samples)
- Value Vector Y
 - This is a row vector – will be explicitly made to have dimensions $(1 \times m)$
- Parameters W and b and gradients
 - For Linear/Logistic regression, W and $\nabla_W L$ are row vectors of length d (number of features) – will be explicitly made to have dimensions $(1 \times d)$
 - b is a scalar – will be explicitly made to have dimensions (1×1)
 - For neural networks W and $\nabla_W L$ will naturally be 2d objects
 - For neural networks, in general, b and $\nabla_b L$ will be column vectors – will be explicitly made to be column vectors – dimensions $(n \times 1)$
- Computed Values A and Z
 - For Linear/Logistic Regression, A and Z are row vectors – will have dimensions $(1 \times m)$
 - For neural networks, A and Z will naturally be 2d objects

4.5 Code Walkthrough

Version 1.1

Coding Walkthrough: Version 1.1

Goal of this Section:

- Walkthrough of initial version of machine learning framework, which includes functionality for forward/back propagation and unit test for derivative testing

Coding Walkthrough: Version 1.1 To Do

File/Component	To Do
NeuralNetwork_Base	Create NeuralNetwork_Base class and methods to be used for both Logistic/Linear Regression and Neural Networks
LRegression	Create class derived from NeuralNetwork_Base with methods specific to Linear and Logistic Regression
functions_loss	Create functions for mean square error loss function and its derivative
functions_activation	Create functions for linear activation and its derivative
unittest_forwardbackprop	Create functions for performing test of derivative calculation

NeuralNetwork_Base Class – Attributes

Variable	Type	Description
nlayer	integer	Number of layers <ul style="list-style-type: none">• Equals 1 for Linear and Logistic Regression• In general greater than 1 for Neural Networks
info	list indices: 0,1,...,nlayer-1	info[k] is a dictionary containing information for layer = k Keys: <ul style="list-style-type: none">• nIn: (integer) number of unit in previous layer (number of features for layer 0)• nOut: (integer) number of units in current layer• activation: (string) activation function type• A: (numpy array) result after activation for current layer• param: (dictionary) parameter matrices (keys W, b)• param_der: (dictionary) derivatives of parameter matrices (keys W, b)• optimizer: (dictionary) optimizer class objects (keys W,b)
loss_fun	string	Name of loss function

NeuralNetwork_Base Class – Methods

Method	Input	Description
get_A	layer (integer)	Return: A, the result of Forward Propagation for specified layer
get_Afinal		Return: A for the final layer
get_param	layer (integer) order (string): “param” or “param_der” label (string): “W” or “b”	Return: parameters W or b or gradients $\nabla_W L$, $\nabla_b L$ for specified layer, order, and label
compile	optimizer (object) loss_fun (string)	Takes in loss function and optimizer object Return: nothing
compute_loss	Y (numpy array)	Return: loss for output (label) vector Y assuming forward propagation has been performed
test_derivative	X (numpy array) Y (numpy array) eps (float)	Return: difference between exact (computed using forward/back propagation) and approximate (computed using centered differences with bump eps) for gradients $\nabla_W L$, $\nabla_b L$

LRegression – Methods

Method	Input	Description
<code>__init__</code>	nfeature (integer) activation (string)	Initialization routine that takes in the number of features and the activation function (“linear” for regression) Return: nothing
<code>forward_propagation</code>	X (numpy array)	Performs forward propagation using feature matrix X to compute result of activation A and stores in info list Returns: nothing
<code>back_propagation</code>	X (numpy array) Y (numpy array)	Performs back propagation using feature matrix X and label vector Y Returns: nothing
<code>concatenate_param</code>	order (string): “param” or “param_der”	Concatenates all entries in W and b or in the their gradient into a single row vector
<code>load_param</code>	flat (numpy array) order (string): “param” or “param_der”	Takes values from flat (row vector) and puts them back into W or b or gradient objects

Activation and Loss Functions

Function	Input	Description
functions_activation. activation	activation_fun (string) Z (numpy array)	Applies specified activation function to entries in Z Return: $f(Z)$
functions_activation. activation_der	activation_fun (string) A (numpy array) grad_A_L (numpy array)	Given activation function, A, and $\nabla_A L$ this function computes $\nabla_Z L$ Return: $\nabla_Z L$
functions_loss. loss	loss_fun (string) A (numpy array) Y (numpy array)	Computes loss function given activation A, label vector Y, and specified function Return: Loss
functions_loss. loss_der	loss_fun (string) A (numpy array) Y (numpy array)	Computes gradient of loss function with respect to elements of A for activation A, label vector Y, and specified function Return: $\nabla_A L$

Unit Test for Forward/Back Propagation

Unit test method has following components:

1. Preparation of Data
 - Create random X and Y
2. Creation of LRegression object
 - Create instance of the LRegression class
3. Compilation
 - Specify loss function and optimizer (None)
4. Run test_derivative method of LRegression object
 - This will compare forward/back propagation derivatives to approximations and return an error (difference)
5. Assert
 - Check if error less than or equal to tolerance (will use 10^{-7})

4.5 Code Version 1.1 Walkthrough DEMO

- Code located at IntroML/Code/Version1.1
- How to proceed:
 - You should attempt to do coding by yourself
 - Use the information about classes and function described in last lecture
 - The examples in the Jupyter notebooks indicate how we will use numpy functionality to convert algorithms into Python code
 - You can look at the files in Version1.1 for hints
 - For the remainder of this lecture, I will do a walkthrough of this initial version of the code and will run the unit test driver

Course Resources at:

- <https://github.com/satishchandrareddy/IntroML/>

4.6 Code Walkthrough

Version 1.2

Coding Walkthrough: Version 1.2

Goal of this Section:

- Walkthrough update of machine learning framework to include functionality for training, prediction, accuracy, and plotting results for linear regression

Coding Walkthrough: Version 1.2 To Do

File/Component	To Do
NeuralNetwork_Base	Add methods for training, prediction, updating parameters, and computing accuracy of prediction
Optimizer_Base	Create Optimizer_Base class
GradientDescent	Create GradientDescent class derived from Optimizer_Base
Plotting	Create function to plot training data, normal equations result, and linear regression prediction as well as accuracy and loss versus epoch
Driver	Create driver for linear regression

NeuralNetwork_Base Class – Methods

Method	Input	Description
compile	loss_fun (string) optimizer_object (class)	Takes in loss function string and optimizer object. Makes a (deep)copy of optimizer object for each W and b in each layer Return: nothing
update_param		Applies optimization approach (Gradient Descent) to update W and b for each layer Return: nothing
fit	X (numpy array) Y (numpy array) epochs (integer)	Applies training algorithm for specified number of epochs using feature matrix X and output information vector Y. Uses approach defined in optimizer input in compile method to compute updates. Return: history dictionary containing loss and accuracy at each epoch
predict	X (numpy array)	Applies prediction algorithm to compute output vector Y for input feature/information matrix X Return: predicted output values
accuracy	Y (numpy array) Y_pred (numpy array)	Computes accuracy comparing label vector Y to predicted results Y_pred Return: accuracy (float)

Optimizer Base and Gradient Descent Class – Methods

Method	Input	Description
<code>__init__</code>	learning_rate (float)	Takes in learning rate α Return: nothing
<code>update</code>	gradient (numpy array)	In general optimizer updates variables using formula: $W_{epoch=i} = W_{epoch=i-1} + Update$ This function computes Update, which for Gradient Descent is $-\alpha \nabla_W L$ Return: update

plot_results

Function	Input	Description
plot_results_history	history (dictionary) key_list (list of strings)	Plots results from training algorithm as a function of epoch. Input history is dictionary containing data to be plotted. This function plots each item represented in key_list on the same plot Return: nothing See IntroML/Examples/Chapter2/MatplotlibBasicsDemo.ipynb
plot_results_linear	model (object) Xtrain (numpy array) Ytrain (numpy array)	Plots results for linear regression, including training data, normal equations solution, and machine learning linear regression prediction. Return: nothing See IntroML/Examples/Chapter4/NormalEquations.ipynb

Linear Regression Driver

Driver has following components:

1. Data
 - Create data or load from external file/program
2. Creation of Model Object
 - Create instance of the LRegression class
3. Compilation
 - Specify optimizer object and loss function
4. Training
 - Input training data X and Y and specify number of epochs
5. Prediction
 - Predict output for new input information X using learned parameters

4.6 Code Version 1.2 Walkthrough DEMO

- Code located at: IntroML/Code/Version1.2
- How to proceed:
 - Using information from previous video, see if you can make updates to framework using an original Version1.1 as starting point
 - Alternatively, watch this video, which walks through updates and then use as a guide to make updates
 - The examples in the Jupyter notebooks indicate how we will use numpy functionality to convert algorithms into Python code

Course Resources at:

- <https://github.com/satishchandrareddy/IntroML/>

4.7 Logistic Regression: Mathematical Foundations

Logistic Regression: Mathematical Foundations

Goal of this Section:

- Extend the mathematical foundations for linear regression to the case of logistic regression, including:
 - Format of input data
 - Function structure and parameters
 - Loss function
 - Training algorithm
 - Prediction algorithm

Logistic Regression and Linear Regression

- Linear Regression used for modeling real values (Y_j are real numbers)
- Logistic Regression used for binary classification (Y_j are labels 0 or 1)
 - Binary classification 2 possibilities – arbitrarily assign 0 to one possibility and 1 to the other (eg cat is 0 and dog is 1, for x-rays 0 is normal and 1 is broken, etc)
- Underlying mathematics and code development for Linear Regression can be extended to Logistic Regression
- Principal Differences between Linear and Logistic Regression:
 - Activation Function:
 - Need suitable activation function to produce 0 or 1 output
 - Linear activation function (can take on values from $-\infty$ to ∞) is not suitable
 - Loss Function
 - Need suitable loss function
 - Mean Squared Error loss function not suitable for Logistic Regression

Motivating Example: Binary Classification

Training Data:

- Input Information: points in (x_0, x_1) plane
- Output Information: label 0 (red) or 1 (blue) for each point

Goal:

- Find function that best fits 0 and 1 labels in training data

Prediction:

- Using function, determine label for new input test points (black points in picture)

Logistic Regression:

- Simple approach for binary classification (builds on Linear Regression)

Motivating Example

- Training data for sample j :

$$\left(\begin{bmatrix} X_{0j} \\ X_{1j} \end{bmatrix}, Y_j \right)$$

Here (X_{0j}, X_{1j}) is the point in the plane and Y_j is the label 0 or 1.

- Define parameters $W = [W_0 \ W_1]$ and b
 $Z_j = WX_j + b = W_0X_{0j} + W_1X_{1j} + b$

- If we choose $W = [1 \ 1]$ and $b = -0.75$,
then appropriate activation function

$$f(Z_j) = \begin{cases} 1 & \text{if } Z_j \geq 0 \\ 0 & \text{if } Z_j < 0 \end{cases}$$

Sigmoid Activation Function

- Step function is not best choice, as we want activation function to be differentiable
- Use instead the sigmoid activation function
$$f(z) = \frac{1}{1 + e^{-z}}$$
- Sigmoid function between 0 and 1
 $f(z) \rightarrow 1$ as $z \rightarrow \text{infinity}$
 $f(z) \rightarrow 0$ as $z \rightarrow -\text{infinity}$

Binary Cross Entropy Loss Function

- Mean Squared Error loss function is not appropriate for logistic regression

- Use Binary Cross Entropy loss function instead:

$$Loss = -[Y \ln(A) + (1 - Y) \ln(1 - A)]$$

- When $Y = 0$, Loss decreases as A goes to 0
- When $Y = 1$ Loss decreases as A goes to 1

Logistic Regression: General Approach

General approach has following components and phases:

- (1) Training Data
- (2) Function Structure
- (3) Loss Function
- (4) Training Phase
- (5) Prediction Phase

Training Data

- Data point j : input information (feature) vector: $\begin{bmatrix} X_{0,j} \\ X_{1,j} \\ \vdots \\ X_{d-1,j} \end{bmatrix}$ and output: Y_j (0 or 1)
- Define the feature matrix ($d \times m$) and output vector ($1 \times m$):

$$X = \begin{bmatrix} X_{00} & \dots & X_{0,m-1} \\ \dots & \dots & \dots \\ X_{d-1,0} & \dots & X_{d-1,m-1} \end{bmatrix} \quad Y = [Y_0 \quad \dots \quad Y_{m-1}]$$

Training Data – Example Points in Plane

- For points in plane with 0 and 1 labels in motivating example, training data consists of points in the plane (X_0, X_1) with label Y
- Suppose 4 data samples with points and labels: $(1,1)$ label=0, $(0.5,2)$ label = 1, $(2,3)$, label = 1, $(4,2)$ label 0
- In this case each sample has 2 features. Feature matrix and value vector are:

$$X = \begin{bmatrix} 1 & 0.5 & 2 & 4 \\ 1 & 2 & 3 & 2 \end{bmatrix} \quad Y = [0 \quad 1 \quad 1 \quad 0]$$

Function Structure – Forward Propagation

Forward Propagation is name applied to process of estimating output values using function structure

1. Input: feature matrix X (dxm d features and m sample points), parameter vector $W = [W_0 \quad \dots \quad W_{d-1}]$ and bias b

2. Linear part: for $j=0, \dots, m-1$

$$Z_j = W_0 X_{0j} + W_1 X_{1j} + W_2 X_{2j} + \dots + W_{d-1} X_{d-1j} + b$$

In vector form

$$Z = WX + b$$

3. Activation: apply sigmoid function $f(z)$ to each element of Z :

$$A_j = f(Z_j) \quad j = 0, \dots, m - 1$$

$$f(z) = \frac{1}{1 + e^{-z}}$$

Logistic Regression Forward Propagation - Example

- Consider a case of 2 features and 3 data points (m=3)

$$X = \begin{bmatrix} 1 & 2 & 4 \\ -2 & -5 & -8 \end{bmatrix} \quad Y = [0 \quad 1 \quad 0]$$

- Assume that initial parameter values are:

$$W = [0.1 \quad 0.1] \quad b = [0.2]$$

- Forward Propagation:

$$Z = WX + b = [0.1 \quad 0.1] \begin{bmatrix} 1 & 2 & 4 \\ -2 & -5 & -8 \end{bmatrix} + [0.2] = [0.1 \quad -0.1 \quad -0.2]$$

$$A = f(Z) = \left[\frac{1}{1+e^{-0.1}} \quad \frac{1}{1+e^{0.1}} \quad \frac{1}{1+e^{0.2}} \right] = [0.5250 \quad 0.4750 \quad 0.4502]$$

Logistic Regression: Loss Function

- Loss function is average of binary cross entropy function over sample points

$$Loss = L = -\frac{1}{m} \sum_{j=0}^{m-1} Y_j \ln(A_j) + (1 - Y_j) \ln(1 - A_j)$$

- For each sample j , only one of $Y_j \ln(A_j)$ or $(1 - Y_j) \ln(1 - A_j)$ is non-zero, as Y_j is 0 or 1

Loss Function - Example

- Consider a case of 2 features and 3 data points (m=3)

$$X = \begin{bmatrix} 1 & 2 & 4 \\ -2 & -5 & -8 \end{bmatrix} \quad Y = [0 \quad 1 \quad 0]$$

- Assume that initial parameter values are:

$$W = [0.1 \quad 0.1] \quad b = [0.2]$$

- From the Forward Propagation Example

$$A = [0.5250 \quad 0.4750 \quad 0.4502]$$

$$L = -\frac{1}{m} \sum_{j=0}^{m-1} Y_j \ln(A_j) + (1 - Y_j) \ln(1 - A_j)$$

$$L = -\frac{1}{3} [\log(1 - 0.5250) + \log(0.4750) + \log(1 - 0.4502)] = 0.6956$$

Training Phase

- Training phase attempts to find suitable coefficients W and b by minimizing loss function when applied to training data
- From multi-variable calculus, Loss function has a local minimum when the gradients are 0

$$\nabla_W L = 0 \text{ and } \nabla_b L = 0$$

- Can solve these equations analytically for Linear Regression, but not in general case (Logistic Regression and Neural Networks)
- Use optimization algorithm (example: Gradient Descent) to minimize Loss function
 - Need to compute the above gradients

Derivative of Loss

- Loss function given by:

$$L = -\frac{1}{m} \sum_{j=0}^{m-1} Y_j \ln(A_j) + (1 - Y_j) \ln(1 - A_j)$$

- Differentiating the log terms, we get:

$$\frac{\partial L}{\partial A_j} = -\frac{1}{m} \left[\frac{Y_j}{A_j} - \frac{1 - Y_j}{1 - A_j} \right], \quad j = 0, \dots, m - 1$$

Derivative of Activation Function

A_j related to Z_j by:

$$A_j = f(Z_j) = \frac{1}{1 + e^{-Z_j}}, \quad j = 0, \dots, m - 1$$

Derivatives given by

$$\frac{\partial A_j}{\partial Z_j} = \frac{e^{-Z_j}}{(1 + e^{-Z_j})^2}, \quad j = 0, \dots, m - 1$$

This can be simplified to:

As we will see when coding,
this format saves memory
as Z need not be saved

$$\frac{\partial A_j}{\partial Z_j} = \frac{e^{-Z_j}}{(1 + e^{-Z_j})^2} = \frac{1 + e^{-Z_j}}{(1 + e^{-Z_j})^2} - \frac{1}{(1 + e^{-Z_j})^2} = A_j - A_j^2$$

Logistic Regression Back Propagation Algorithm

Input: feature matrix X and value vector Y

1. Compute:

$$\nabla_A L = \left[\frac{\partial L}{\partial A_0} \quad \frac{\partial L}{\partial A_1} \quad \cdots \quad \frac{\partial L}{\partial A_{m-1}} \right], \quad \frac{\partial L}{\partial A_j} = -\frac{1}{m} \left[\frac{Y_j}{A_j} - \frac{1-Y_j}{1-A_j} \right], j = 0, \dots, m-1$$

3. Compute derivatives of A: $\frac{\partial A_j}{\partial Z_j} = A_j - A_j^2, j = 0, \dots, m-1$

4. Compute gradient L with respect to Z:

$$\nabla_Z L = \nabla_A L * \left[\frac{\partial A_0}{\partial Z_0} \quad \frac{\partial A_1}{\partial Z_1} \quad \cdots \quad \frac{\partial A_{m-1}}{\partial Z_{m-1}} \right] \text{ (component-wise multiplication)}$$

5. Compute gradient of L with respect to W and b (from Section 3.2):

$$\nabla_W L = \nabla_Z L X^T, \quad \nabla_b L = \sum_{j=0}^{m-1} \nabla_Z L_j$$

Logistic Regression Back Propagation - Example

- Consider a case of 2 features and 3 data points ($m=3$)

$$X = \begin{bmatrix} 1 & 2 & 4 \\ -2 & -5 & -8 \end{bmatrix} \quad Y = [0 \quad 1 \quad 0]$$

- Assume that initial parameter values are:

$$W = [0.1 \quad 0.1] \quad b = [0.2]$$

- From Forward Propagation Example

$$A = [0.5250 \quad 0.4750 \quad 0.4502]$$

- Gradient of Loss with respect to A:

$$\nabla_A L = -\frac{1}{3} \left(\frac{Y}{A} - \frac{1-Y}{1-A} \right) = -\frac{1}{3} \begin{bmatrix} -\frac{1}{1-0.5250} & \frac{1}{0.4750} & -\frac{1}{1-0.4502} \end{bmatrix} = [0.7017 \quad -0.7017 \quad 0.6062]$$

$$\frac{\partial A_j}{\partial Z_j} = A_j - A_j^2 \quad \begin{bmatrix} \frac{\partial A_0}{\partial Z_0} & \frac{\partial A_1}{\partial Z_1} & \frac{\partial A_2}{\partial Z_2} \end{bmatrix} = [0.2494 \quad 0.2494 \quad 0.2475]$$

$$\nabla_Z L = \nabla_A L * \begin{bmatrix} \frac{\partial A_0}{\partial Z_0} & \frac{\partial A_1}{\partial Z_1} & \frac{\partial A_2}{\partial Z_2} \end{bmatrix} = [0.7017 \quad -0.7017 \quad 0.6062] * [0.2494 \quad 0.2494 \quad 0.2475] = [0.1750 \quad -0.1750 \quad 0.1501]$$

$$\nabla_W L = \nabla_Z L X^T = [0.1750 \quad -0.1750 \quad 0.1501] \begin{bmatrix} 1 & -2 \\ 2 & -5 \\ 4 & -8 \end{bmatrix} = [0.4252 \quad -0.6755]$$

$$\nabla_b L = \sum_{j=0}^{m-1} \nabla_Z L_j = 0.1501 \quad (\text{sum of entries of } \nabla_b L)$$

Training Algorithm

- Other than change for activation function and loss function, Training Algorithm for Logistic Regression is the same as that for Linear Regression

Prediction Algorithm

Prediction algorithm makes use of parameters computed in Training Algorithm

Input new input feature matrix \tilde{X}

Use W and b computed by Training Algorithm

1. Perform Forward Propagation to determine \tilde{A}
 - Round \tilde{A} to closest number 0 or 1 to get predicted label
- Can regard each entry of prediction vector \tilde{A} as probability that prediction is 1. ($1 - \tilde{A}$ is probability that prediction is 0.)

Logistic Regression Prediction - Example

- Consider a case of 2 features and 3 data points ($m=3$)

$$X = \begin{bmatrix} 1 & 2 & 4 \\ -2 & -5 & -8 \end{bmatrix} \quad Y = [0 \quad 1 \quad 0]$$

- Assume that initial parameter values are:

$$W = [0.1 \quad 0.1] \quad b = [0.2]$$

- From the Forward Propagation Example slide

$$A = f(Z) = \left[\frac{1}{1+e^{-0.1}} \quad \frac{1}{1+e^{0.1}} \quad \frac{1}{1+e^{0.2}} \right] = [0.5250 \quad 0.4750 \quad 0.4502]$$

- Round to 0 or 1 (round 0.5 up to 1) – predicted labels: $[1 \quad 0 \quad 0]$

Accuracy Calculation

Accuracy calculation compares actual vector label to predicted values

1. Perform Training
2. Let \tilde{X} denote feature matrix and \tilde{Y} denote related value vector (these may be same as used in training or completely different)
3. Apply prediction algorithm to \tilde{X} to get predicted value vector \tilde{P}
4. Accuracy defined by:

$$Accuracy = \frac{1}{m} \sum_{j=0}^{m-1} (1 \text{ if } \tilde{P}_j = \tilde{Y}_j, 0 \text{ otherwise})$$

- Both value vector and predicted valued vector consist of 0 or 1 entries.
Accuracy = 1 means prediction equals initial value vector for all entries.
Accuracy = 0 means none of the entries in prediction vector match those in original value vector.

Accuracy Calculation - Example

- Suppose that

$Y = [0 \quad 1 \quad 1 \quad 0 \quad 1]$ and predicted values after rounding = $[1 \quad 0 \quad 1 \quad 0 \quad 1]$

- Accuracy calculation: Y matches predicted values for 3 out of 5 entries, so

Accuracy = 0.6

Logistic Regression – Summary

Component	Subcomponent	Details
Training Data		Input m data points: X (dxm-dimensional feature matrix) Y vector of labels (0 or 1) (row vector of length m)
Function Structure	Forward Propagation	Linear: $Z = WX + b$ (Z is row vector of length m, W is row vector of length d, b is scalar) Activation function: $f(Z) = \frac{1}{1+e^{-Z}}$ $A = f(Z)$ (1xm vector)
Loss Function		Binary Cross Entropy: $L = -\frac{1}{m} \sum_{j=0}^{m-1} Y_j \log A_j + (1 - Y_j) \log(1-A_j)$
Derivative	Back Propagation	Compute $\nabla_W L$ and $\nabla_b L$
Training Algorithm	Train using Gradient Descent to minimize Loss	Find W, b that minimizes loss Initial epoch: $W_{epoch=0}, b_{epoch=0}$ Choose Learning Rate: $\alpha > 0$ For each epoch: (apply forward and back propagation to compute gradients) $W_{epoch=i} = W_{epoch=i-1} - \alpha \nabla_W L_{epoch=i-1}$ $b_{epoch=i} = b_{epoch=i-1} - \alpha \nabla_b L_{epoch=i-1}$ Perform fixed number of iterations or until Loss reduced sufficiently
Prediction Algorithm	Apply Forward Propagation	Using computed W and b from Training Algorithm Given new input feature matrix \tilde{X} Perform Forward Propagation to compute \tilde{A} and round to (0 or 1) to get predicted label

4.7 Logistic Regression – Jupyter Notebook DEMO

- Open file IntroML/Examples/Chapter4/LogisticRegression.ipynb
- Has example of
 - Forward Propagation
 - Loss Function
 - Back Propagation
 - Prediction
 - Accuracy calculation

Course Resources at:

- <https://github.com/satishchandrareddy/IntroML/>

4.8 Code Walkthrough: Version 1.3

Code Walkthrough Version 1.3

Goal of this Section:

- Walkthrough extension of machine learning framework to handle logistic regression

Coding Walkthrough: Version 1.3 To Do

File/Component	To Do
NeuralNetwork_Base	Update accuracy and prediction methods to handle binary cross entropy case
functions_loss	Add functionality for binary cross entropy and its derivative
functions_activation	Add functionality for sigmoid activation and its derivative
plotting	Add routine for plotting training data and prediction heatmap in x0-x1 plane for classification
example_classification	Add function to generate training data for classification
unittest_forwardbackprop	Add method for testing logistic regression case
driver_logisticregression	Driver for logistic regression

NeuralNetwork_Base Class – Methods

Method	Input	Description
accuracy	Y (numpy array) Y_pred (numpy array)	Add functionality for “binarycrossentropy” loss Return: accuracy (float) See: IntroML/Examples/Chapter4/LogisticRegression.ipynb
prediction	X (numpy array)	Add functionality for “binarycrossentropy” loss Return: prediction See: IntroML/Examples/Chapter4/LogisticRegression.ipynb

Activation and Loss Functions

Function	Input	Description
functions_activation. activation	activation_fun (string) Z (numpy array)	Update to handle case of “sigmoid” activation Return: $f(Z)$ See: IntroML/Examples/Chapter4/LogisticRegression.ipynb
functions_activation. activation_der	activation_fun (string) A (numpy array) grad_A_L (numpy array)	Update to handle case of “sigmoid” activation Return: $\nabla_Z L$ See: IntroML/Examples/Chapter4/LogisticRegression.ipynb
functions_loss. loss	loss_fun (string) A (numpy array) Y (numpy array)	Update to handle case of “binarycrossentropy” loss function Return: Loss See: IntroML/Examples/Chapter4/LogisticRegression.ipynb
functions_loss. loss_der	loss_fun (string) A (numpy array) Y (numpy array)	Update to handle case of “binarycrossentropy” loss Return: $\nabla_A L$ See: IntroML/Examples/Chapter4/LogisticRegression.ipynb

plot_results

Function	Input	Description
plot_results_data	data_train (tuple containing training data X,Y) nclass (integer)	Plots the training data in X0-X1 plane (Y=0 plotted red, Y=1 plotted blue, ...) Return: nothing See IntroML/Examples/Chapter2/MatplotlibHeatmapDemo.ipynb
plot_results_heatmap	model (object) Xtrain (numpy array)	Plots a heatmap of the results of logistic regression given the logistic regression model and the training feature matrix Return: nothing See IntroML/Examples/Chapter2/MatplotlibHeatmapDemo.ipynb
plot_results_classification	model (object) data_train (tuple containing training data X,Y) nclass (integer)	Calls plot_results_data and plot_results_heatmap described above Return: nothing

example_classification

Method	Input	Description
example	nfeature (integer) m (integer) case (string) nclass (integer)	Function to generate training data X,Y given number of features, number of samples, case, and number of classes Return: X,Y

4.8 Code Version 1.3 Walkthrough DEMO

- Code located at: IntroML/Code/Version1.3
- How to proceed:
 - Using information from previous videos, see if you can make updates to framework using an original Version1.2 as starting point
 - Alternatively, watch this video, which walks through updates and then use as a guide to make updates
 - The examples in the Jupyter notebooks indicate how we will use numpy functionality to convert algorithms into Python code
